The Rainwater Tank

A Potential Breeding Aid For Disease

The domestic rainwater tank, adopted by many across Australia in recent years as an environmentally-conscious water-saving tool is more readily being seen as an aid for the breeding of a potentially disease-carrying insect – the mosquito.

Specific species of mosquitoes are carriers of debilitating and in, some instances, fatal diseases, which, via a mosquito bite, can be readily transferred to humans. Within Australia, these diseases, include:

- Barmah Forest Virus
- Dengue Fever
- Japanese Encephalitis
- Malaria
- Murray Valley Encephalitis
- Ross River Fever.

Key to control of these potential disease-carrying mosquitoes is to eliminate their breeding sites in and around your home – Rainwater Tank maintenance should be high on your list of priorities.

MozziRid, developed and distributed exclusively by ClayTech/Outdoor Power Products, is a key

aid to rainwater tank maintenance, preventing the breeding capability of all mosquito species within your tank.

Mode of Action

MozziRid, in a pre-prepared liquid form, is added to the contents of your rainwater tank, which in affect, alters the surface-tension of the water. The change in surface tension does not allow the mosquito to land upon the water to lay their eggs (i.e. they sink) and larvae, perhaps already present, within the contents of tank, are prevented from breathing, as they are unable to break the surface.

MozziRid

- Treats your rainwater tank in a single dose
- Non-toxic to human, animal or plant life.
